Aim: Implement a program that demonstrates the concepts of class and objects

Objective: To develop the ability of converting real time entity into objects and create their classes.

Theory:

A class is a user defined blueprint or prototype from which objects are created. It represents the set of properties i.e., members and methods that are common to all objects of one type. In general, class declarations can include these components, in order:

1. Modifiers: A class can be public or has default access.
2. class keyword: class keyword is used to create a class.
3. Class name: The name should begin with a initial letter (capitalized by convention).
4. Superclass (if any): The name of the class's parent (superclass), if any, preceded by the keyword extends. A class can only extend (subclass) one parent.
5. Interfaces (if any): A comma-separated list of interfaces implemented by the class, if any, preceded by the keyword implements. A class can implement more than one interface.
6. Body: The class body surrounded by braces, { }.

An OBJECT is a basic unit of Object-Oriented Programming and represents the real-life entities. A typical Java program creates many objects, which interact by invoking methods. An object consists of:

1. State: It is represented by attributes of an object. It also reflects the properties of an object.
2. Behavior: It is represented by methods of an object. It also reflects the response of an object with other objects.
3. Identity: It gives a unique name to an object and enables one object to interact with other objects.

Code:

1}

```
class Rectangle{  
    int length;  
    int width;  
    void insert(int l, int w){  
        length=l;  
        width=w;  
    }  
    void calculateArea(){System.out.println(length*width);}  
}  
class TestRectangle1{  
    public static void main(String args[]){  
        Rectangle r1=new Rectangle();  
        Rectangle r2=new Rectangle();  
        r1.insert(7,9);  
        r2.insert(5,12);  
        r1.calculateArea();  
        r2.calculateArea();  
    }  
}
```

```

Conclusion:

1) Comment on how you create a class template and their objects.

Creating a class template and objects in Java is fundamental to object-oriented programming. Here's an overview of how you create a class template and instantiate objects from it:

1. Create a Class Template:

A class in Java serves as a blueprint or template for creating objects. It defines the structure and behavior of objects of that class. To create a class template, you use the `class` keyword followed by the class name and a code block containing fields (variables) and methods (functions).

2. Create Objects (Instances):

Once you've defined a class template, you can create objects, also known as instances, of that class. Objects represent specific instances of the class with their own values for the fields. You use the `new` keyword to create objects.

Access Fields and Methods:

Use the dot notation to access fields and call methods of the object.
